Outline

- Background
- Objectives
- Field Infiltration Tests
- Modeling Framework
- Results and Conclusions
- Future Work

Urban Stormwater Runoff

As a result of an expansion of impervious surfaces in the urban areas, **urban stormwater runoff** is generated when precipitation events flow over impervious surface and water does not percolate into the ground. Excess water in storm drains contributes to combined sewer overflows (CSOs) and urban waterway pollution.

- GI uses trees and other vegetation in urban and suburban areas are used to manage and treat precipitation naturally.
- GI preserves natural systems and uses engineered systems such as porous paving, rain barrels, green roofs, rain gardens, and vegetated swales.

Objectives

The objective of this study is to develop a stormwater model, which would quantify the changes of stormwater runoff resulting from Green Infrastructure (GI) implementations.

Infiltration Rate Tests of Porous Paving

Modeled Runoff

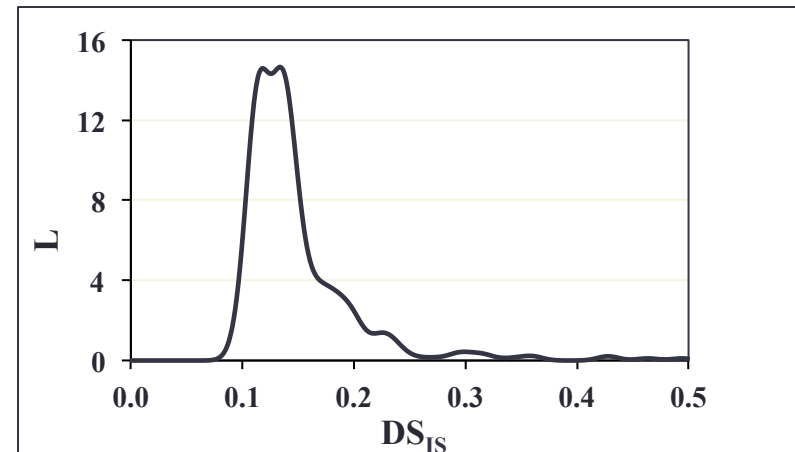

Modeled Runoff

Optimal Parameters

- The GI parameters were calibrated using the incorporated model calibration procedure. And the optimal parameter values (with corresponding confidence level) was applied to simulate the GI effect.

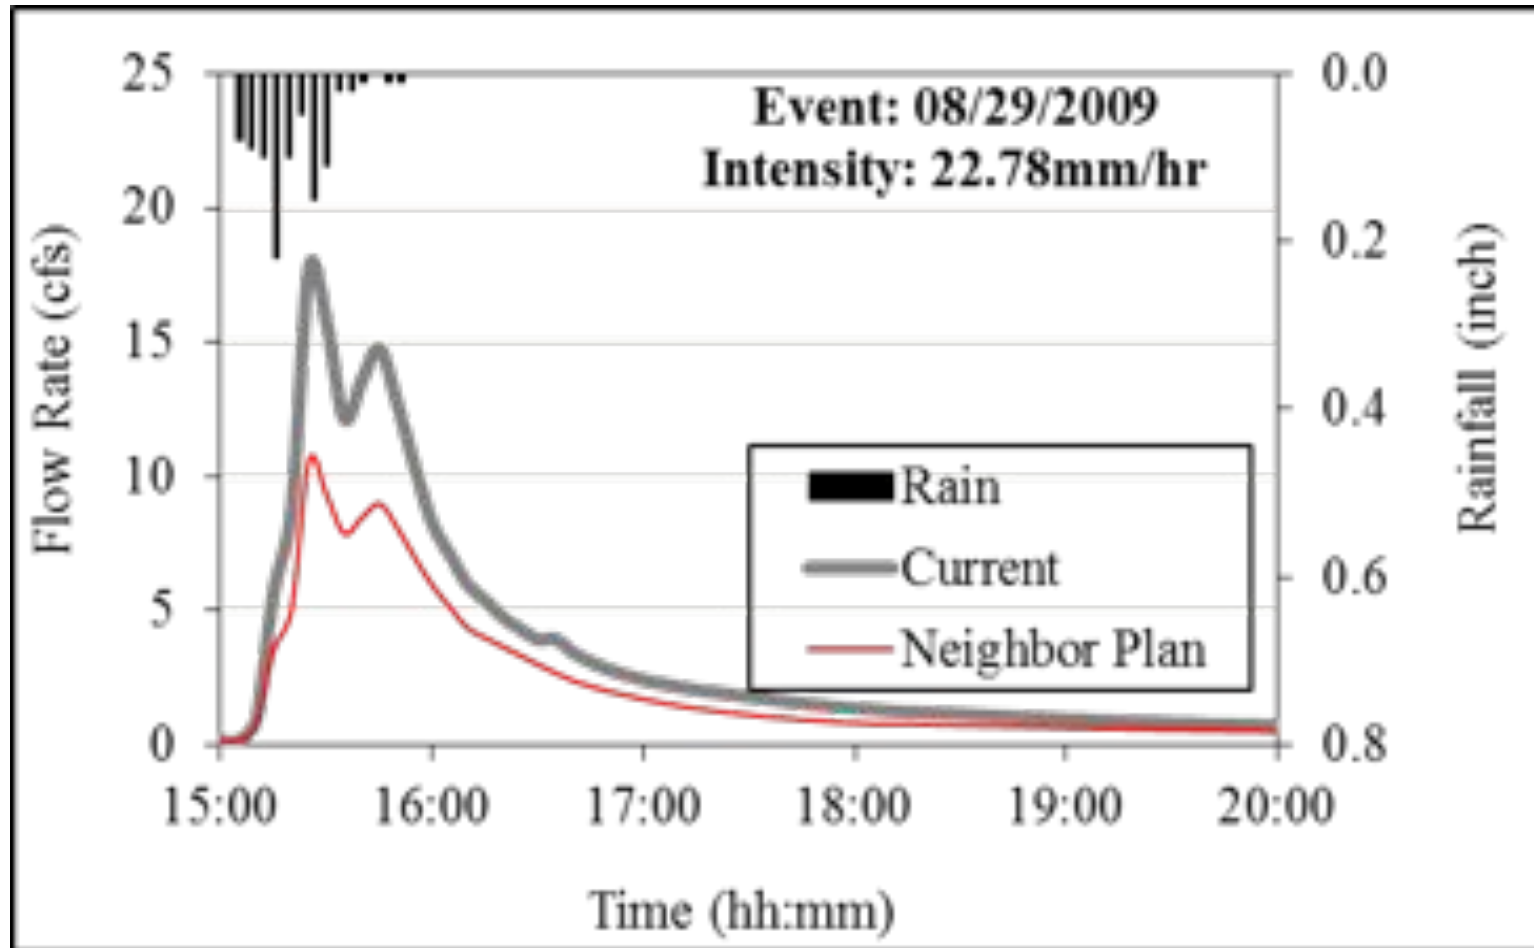

Modeling GI Effect

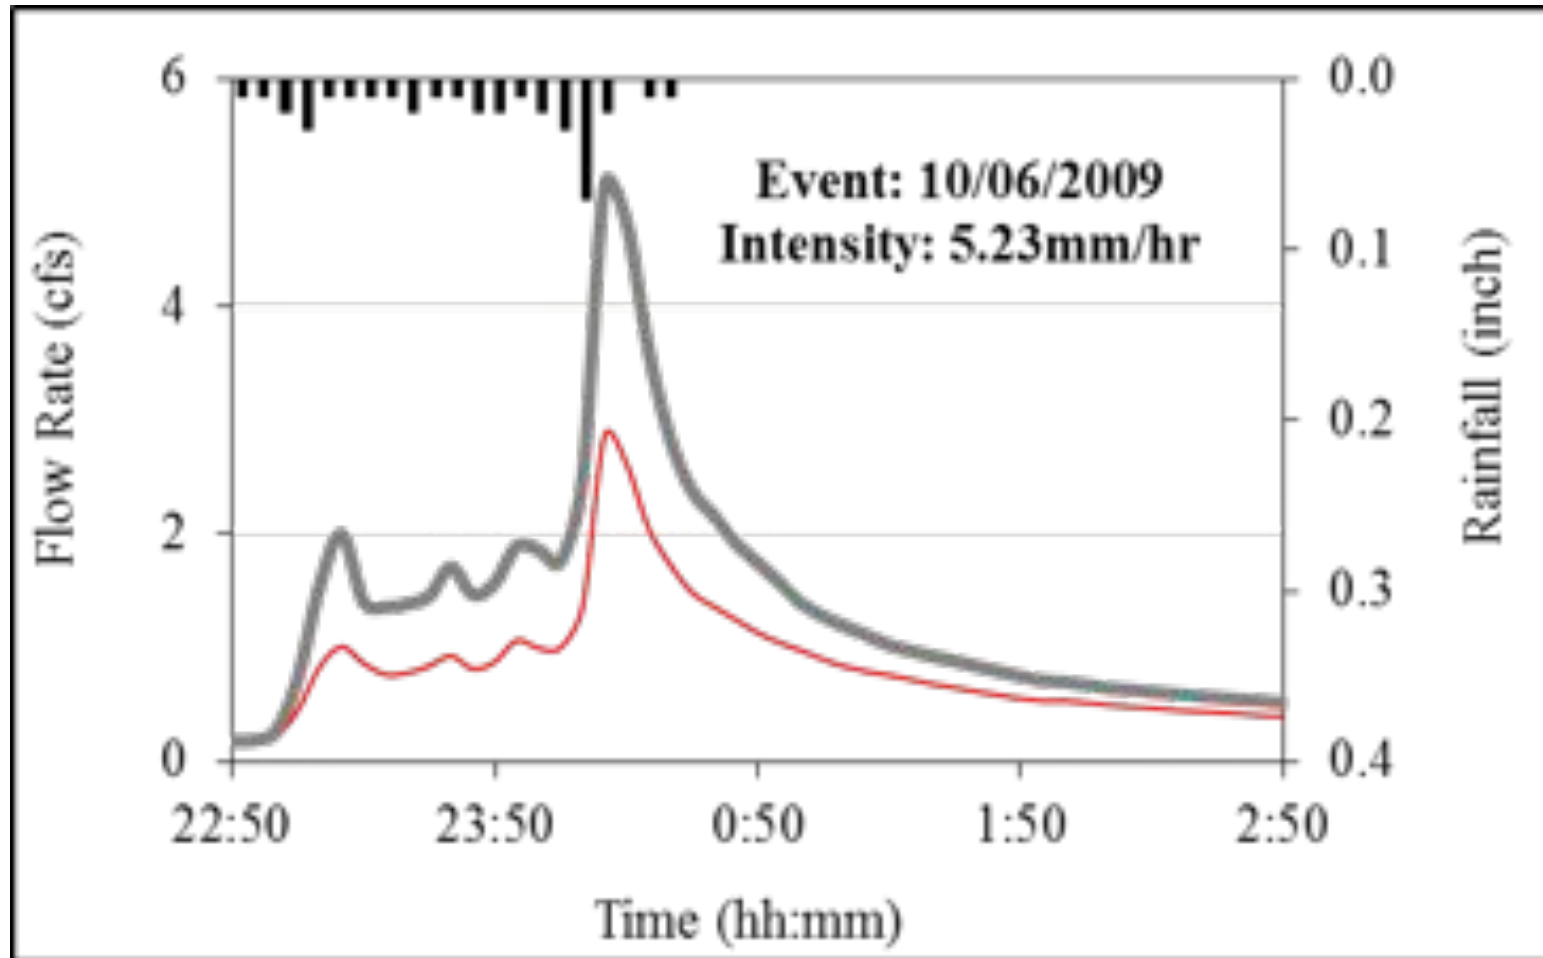

Scenario: Plant Trees in the Neighborhood:

We assume that 80% of the residents in the studied site would be willing to plant trees in their backyard and trees would cover 50% of available space in the participants' backyard (The area of trees increased by 9% of the total study area).

Some Modeling Results

Some Modeling Results

Future Work

Integrate citizen knowledge, attitudes, and behavioral intention towards GI in the stormwater model to project the potential urban storm water runoff reduction from future GI implementations.

Thanks!

A simple black and white line drawing of a smiling face with its arms raised in a gesture of praise or excitement. The drawing is positioned below the word "Thanks!".
